Between-chip normalization: Scale normalization

- A popular method for between-chip normalization of cDNA chips.
- **What it does:** It makes the range of values in each chip similar to each other.
- **Rationale:** It can be assumed that the range of most gene's expression values do not change across replicates and samples.
- **How it works:** Calculate a scaling factor for each chip and divide values in each chip.

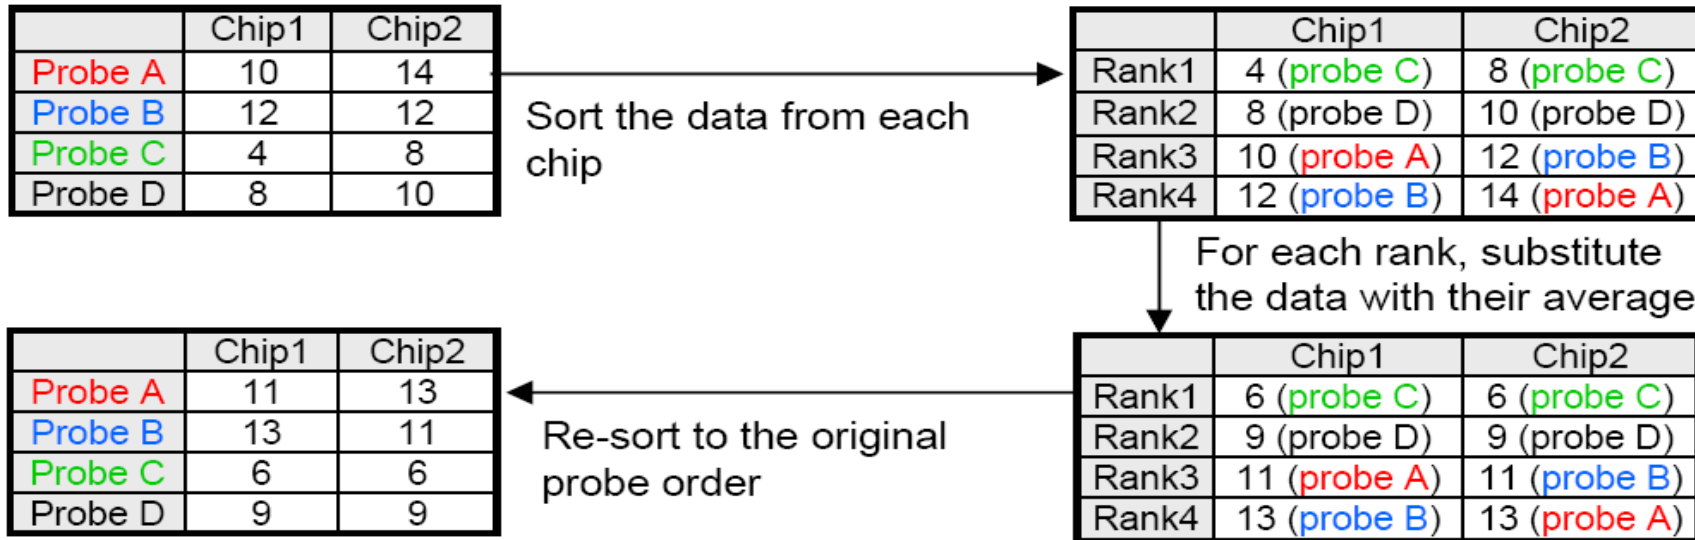

An extra: Detailed procedure as implemented in limma package

1. For each column in the expression data table, get the median of absolute values. Then apply \log_2 transform.
2. Get the mean of n column medians.
3. Calculate a scaling factor for each column ($=2^{\text{col_median}} / 2^{\text{mean_of_col_medians}}$)
4. Divide values in each column by its scaling factor.
5. Steps 1-4 are applied to "M" and "A" separately

Between-chip normalization: Quantile normalization

- Use this for both one-channel array (and two-channel array also).
- **What it does:** Make the replicate arrays to have equal distribution.
- **Rationale:** It can be assumed that distribution of expression values does not change much across all replicates and samples under study.
- **How it works:** Values for each column are ranked, then the average per rank is taken and is reattributed to each column according to the original rank.

Through quantile normalization, all replicate chips get the same distribution. That is,

- The most expressed genes in each chip get the same value.
- The second most expressed genes in each chip get the same value.
- ...
- The least expressed genes in each chip get the same value.

17

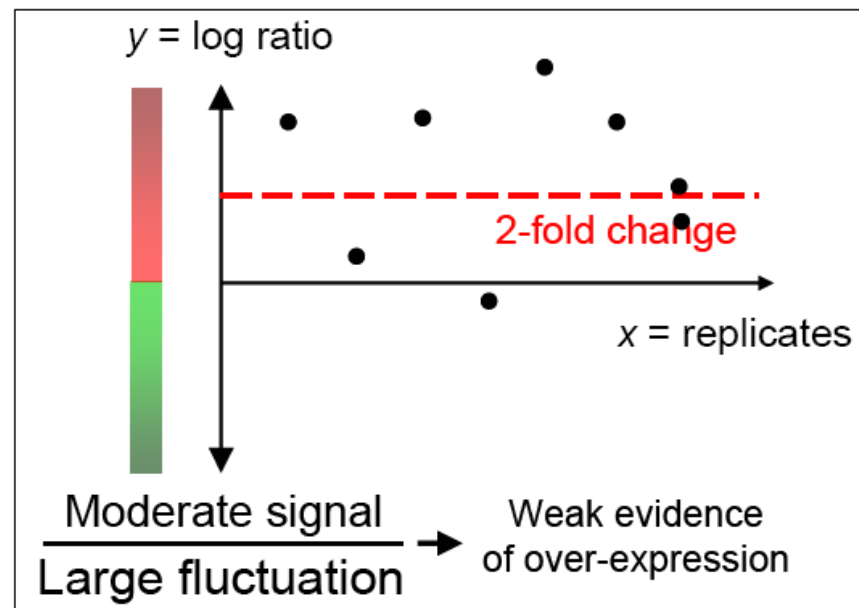

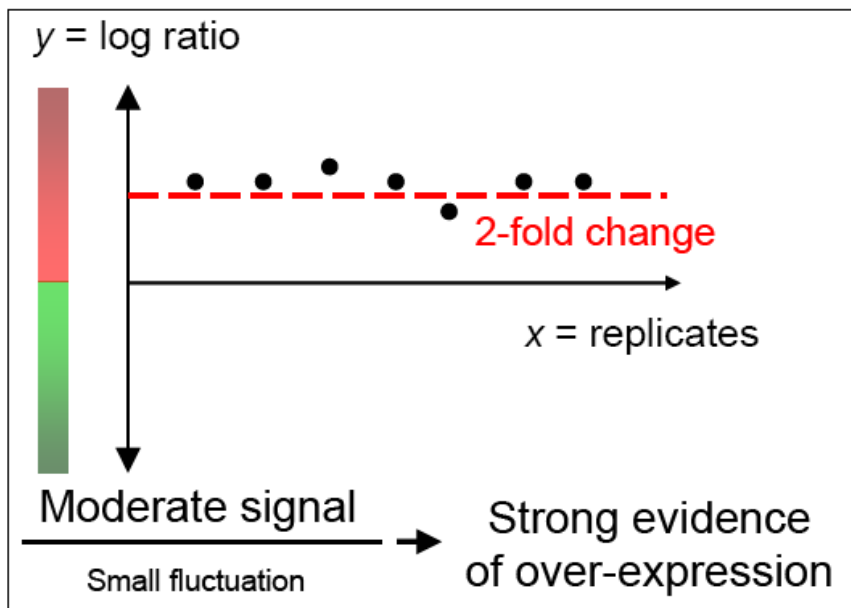

RMA = Quantile normalization + Probe set summarization by Tukey's median polish

数据的初步分析 — 差异基因的选择

➤ 一般来说， $\text{ratio} > 2$ 或 $\text{ratio} < 0.5$ 认为是在两种样本表达有差异。

- **Signal:** Average of log ratios (Average fold change)
 - **Noise:** Fluctuation (or inconsistency) across replicates
- } **Signal-to-noise ratio:** t -statistic

PARAMETRIC & NON-PARAMETRIC TESTS

Three types of tests for differential expression

Parametric test

1. *t*-test

- Unpaired *t*-test
- Paired *t*-test

Observed
t-statistic

Non-parametric test (\approx Distribution-free test)

2. Classical non-parametric test

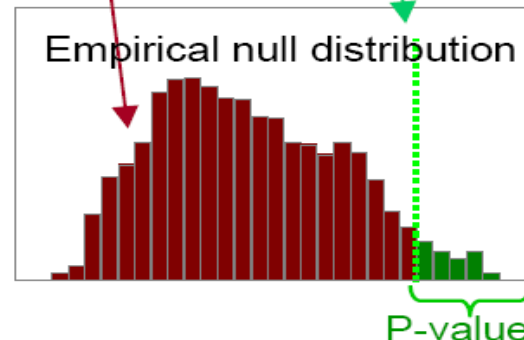

- Wilcoxon rank-sum test (aka Mann-Whitney test)
- Wilcoxon signed rank test

3. Permutation test

- SAM (Significance Analysis of Microarrays)

Generate empirical
null distribution
through permutation

Observed
t-statistic

Terminology

- Parameter: Any characteristic of a population.
- Parametric test: We assume that the population follows normal distribution.
- P-value: Probability of getting an event as extreme as, or more extreme than the observed event, given that null hypothesis is true. Small P-value indicates more evidence of differential expression

Do statistical test for each probe

Do statistical test with normalized and log transformed data table, for each probe

	Replicate control chips			Replicate case chips		
	Rep 1	Rep 2	...	Rep 1	Rep 2	...
Probe 1	5	5.2	...	6.1	6.3	...
Probe 2	4.1	3.9	...	4.1	4.0	...
Probe 3	6.5	6.3	...	4.5	4.3	...
...
Probe N	2.2	2.4	...	2.5	2.2	...

(1) Do test for probe 1 to get its P-value, statistic, and average fold change

	Rep 1	Rep 2	...	Rep 1	Rep 2	...
Probe 1	5	5.2	...	6.1	6.3	...
Probe 2	4.1	3.9	...	4.1	4.0	...
Probe 3	6.5	6.3	...	4.5	4.3	...
...
Probe N	2.2	2.4	...	2.5	2.2	...

(2) Do test for probe 2 to get its P-value, statistic, and average fold change

... (N) Repeat until the last probe N

多重假设检验

- 在进行差异基因挑选时，整个差异基因筛选过程需要做成千上万次假设检验，导致假阳性率的累积增大。对于这种多重假设检验带来的放大的假阳性率，需要进行纠正。
- Bonferroni
 - p/n
- False Discovery Rate (FDR): Benjamini
 - $q=p*n/rank$

FDR、Q VALUE、ADJUSTED P VALUE

- P value: 衡量假阳性率的指标 (False positive rate)
-
- q value: 衡量错误发现率的指标 (False discovery rate, FDR) 使用Q value的这个参数预估FDR, 通常又被称为adjusted p value。
- $Q\ value = FDR = adjusted\ p\ value$

MAQC I, II

- provide quality control (QC) tools to the microarray community to avoid procedural failures
- develop guidelines for microarray data analysis by providing the public with large reference datasets along with readily accessible reference RNA samples
- establish QC metrics and thresholds for objectively assessing the performance achievable by various microarray platforms
- evaluate the advantages and disadvantages of various data analysis methods
- reach consensus on the “best practices” for development and validation of predictive models based on microarray gene expression and genotyping data for personalized medicine.

MAQC INTER AND INTRA PLATFORM REPRODUCIBILITY

- For the 5 commercial microarray platforms, the minimum overlap is at least 60%
- many achieving >80% between platforms
- >90% within a platform

The MicroArray Quality Control (MAQC) project shows inter- and intraplatform reproducibility of gene expression measurements

MAQC Consortium*

Over the last decade, the introduction of microarray technology has had a profound impact on gene expression research. The publication of studies with dissimilar or altogether contradictory results, obtained using different microarray platforms to analyze identical RNA samples, has raised concerns about the reliability of this technology. The MicroArray Quality Control (MAQC) project was initiated to address these concerns, as well as other performance and data analysis issues. Expression data on four titration pools from two distinct reference RNA samples were generated at multiple test sites using a variety of microarray-based and alternative technology platforms. Here we describe the experimental design and probe mapping efforts behind the MAQC project. We show intraplatform consistency across test sites as well as a high level of interplatform concordance in terms of genes identified as differentially expressed. This study provides a resource that represents an important first step toward establishing a framework for the use of microarrays in clinical and regulatory settings.

Options

Profile graph

R script

▼ Quick start

- Specify a GEO Series accession and a Platform if prompted.
- Click 'Define groups' and enter names for the groups of Samples you plan to compare, e.g., test and control.
- Assign Samples to each group. Highlight Sample rows then click the group name to assign those Samples to the group. Use the Sample metadata (title, source group).
- Click 'Top 250' to perform the calculation with default settings.
- Results are presented as a table of genes ordered by significance. The top 250 genes are presented and may be viewed as profile graphs. Alternatively, the cr
- You may change settings in Options tab.

GEO2R

○ distribution

GEO2R

Value distribution

Options

Profile graph

R script

Calculate the distribution of value data for the Samples you have selected. Distributions may be viewed graphically as a [box plot](#) or exported as a [number summary](#) table. The plot is useful for determining if value data are median-centered across Samples, and thus suitable for cross-comparison. [More...](#)
